PREFACE

Vermont Population Projections, 1990-2005 is presented to serve the planning needs of state and local government. This publication is one of a series produced by the Office of Policy Research and Coordination and the Department of Health. The last such set of projections was produced in 1983. Since that time, two important changes have taken place. Migration into the state has increased to levels similar to those in the mid-1970's, and birth rates, particularly for women under the age of 30, have declined.

Vermont's population will continue to grow from a July, 1988 total of approximately 556,000 to between 617,000 and 689,000 by the year 2005. This represents a growth rate of between 0.7 and 1.3 percent. The growth compares with a rate of 1 percent in the 1980's and 1.4 percent in the 1970's. The possibility that future Vermont growth may be less than in the last two decades is due to lower birth rates and the aging of the Baby Boom generation out of its prime child-bearing years. The range of projected growth rates corresponds to different potential migration rates.

The 1990-2005 projections take new population data from the last eight years and provide a base from which planners can work to evaluate future needs and trends. The projections are based on historical trends and an age-cohort model. Generally, the projections do not attempt to identify future changes in local conditions due to policy or specific developments. A large plant closing or a new housing development can have dramatic effects on individual town or city populations that have not been incorporated into these projections. Therefore, it is the responsibility of the planner to identify major events that may affect future populations and include them with these base line projections while making planning decisions.

These projections are presented as a high and low series of population estimates. The high and low projections offer a range which provides a degree of certainty for estimating future population. The state totals have a higher degree of certainty than do the county and town figures, as local events may cause large percentage fluctuations in town populations. The fluctuations are moderated when considered over a larger population base.

Both state and county totals have a higher degree of certainty than do the age-cohort projections. Small sample size and a lack of age-cohort data since 1980 cause the greater uncertainty in the cohort subsets.

All of the population estimates in this report are for full-time residents. This fact is important for planners hoping to determine the needs for future services. Towns with a high proportion of seasonal residents may show growth patterns quite different from the projected changes in full-time residents.

A description of the methods is included at the end of this report. For further information concerning the projections, contact Ken Jones at the Office of Policy Research and Coordination, (802) 828-3326.

7. Projected population of Vermont towns, 1987-2005. 36

SUMMARY

The population in the State of Vermont should grow at an annual growth rate of between 0.7 and 1.3 percent for the years 1989 through 2005. Each of the 14 counties should experience population growth although the counties in the Champlain Valley (Addison, Chittenden, Franklin and Grand Isle) are projected to show the greatest increases (Figures 1 and 2, Table 1).

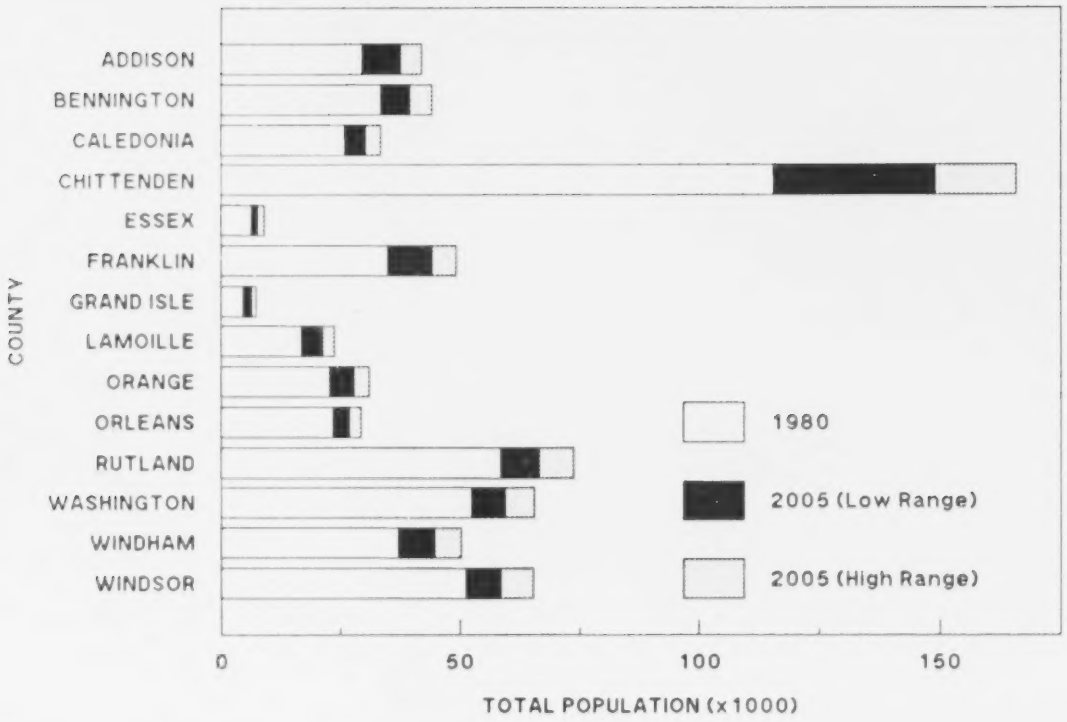

Figure 1. Population of Vermont counties, 1980-2005.

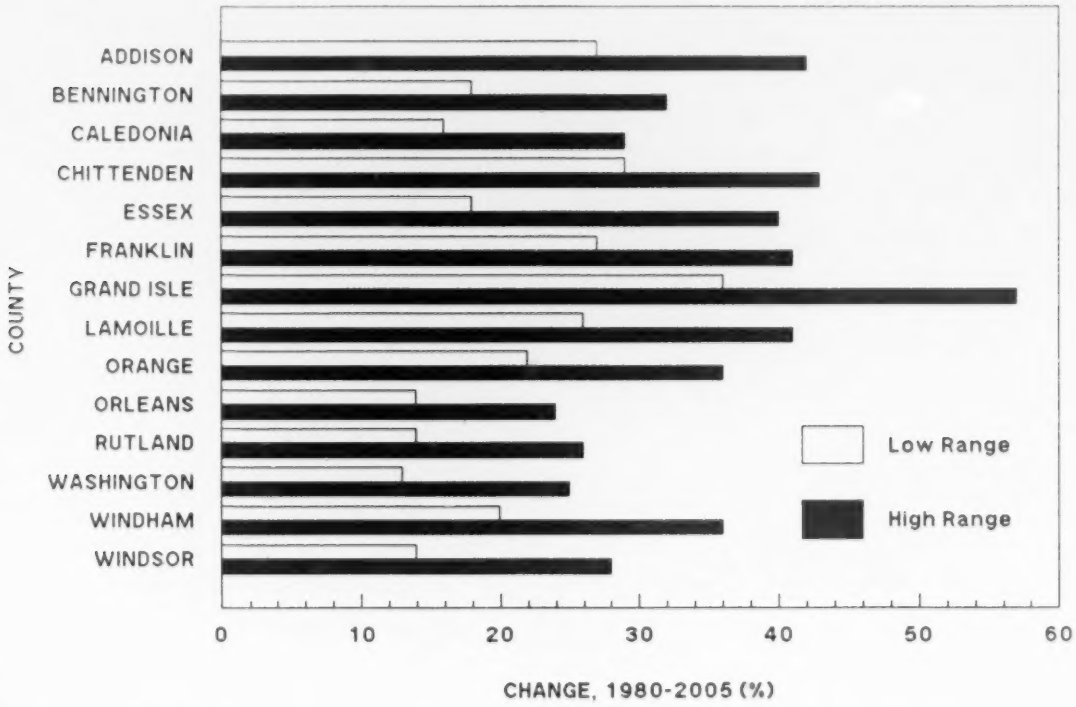

Figure 2. Population growth of Vermont counties, 1980-2005.

The birth rates for each county are expected to follow the same county-by-county trends that have been observed through the 1980's by the Department of Health and reported in its annual publication of vital statistics. For most age cohorts, the birth rates are expected to remain at current levels because downward pressures on fertility rates have slowed and upward pressures are possible (Table 2). The projections do assume that the fertility rate for women aged 15-19 will decrease as a result of education and outreach programs[1]. Since 1980, the birth rate for this teenage cohort has decreased almost 20 percent due, in part, to the successes of past programs.

The survival rates, unlike the fertility rates, do not show a strong dependence on the county of residence. For this reason, one set of survival rates was used for all of the calculations (Table 3).

Migration is a key component of future population growth in Vermont's towns and cities. This set of projections uses different assumptions regarding migration for the high and low series. The low series population projections assume Vermont's net in-migration will be a constant 1,520 persons annually. This assumption is based on the ten-year average in-migration between 1977 and 1987. The rates of in-migration during the late 1980's have been higher than the assumed rate, but changes in economic conditions, state policies and personal preferences could result in a slowing of in-migration resulting in a long term average rate similar to historical figures. The high series population projections assume that net in-migration will continue to increase to a level of 6,448 by the year 2000.

The only difference between the high and low series is the migration component. This is a useful statistical approach only and does not mean that the fertility and survival assumptions are made with absolute certainty. The result of the projections is that variations in fertility rate, coupled with changes in assumed migration rate should lead to population totals that fall between the high and low series projections.

Different counties have experienced different rates of migration (Table 4). In the future, it is difficult to project how geographic migration patterns will develop. For the purpose of these projections, current migration patterns are assumed to gradually change so that the total state in-migration will be spread evenly among counties by the late 1990's. The technical description of this calculation is included in the methods section of this report. Future migration numbers are susceptible to rapid change and planners should account for possible local and regional differences due to new developments.

The effects of the post World War II Baby Boom will continue to be important in the demographic structure of Vermont, and will cause significant changes in that structure by 2005 (Figure 3). In the 1990's, the number of Vermonters in the 40-49 year-old age group will increase rapidly, reflecting the aging of the Baby Boomers (Table 5). The number of young adults ages 20-29 will decrease, the first time this phenomenon has been observed in Vermont since the 1950's (Table 5).

---

[1]The birth rate for young women aged 15-19 is expected to decrease by 1 percent annually from the 1988 figure.

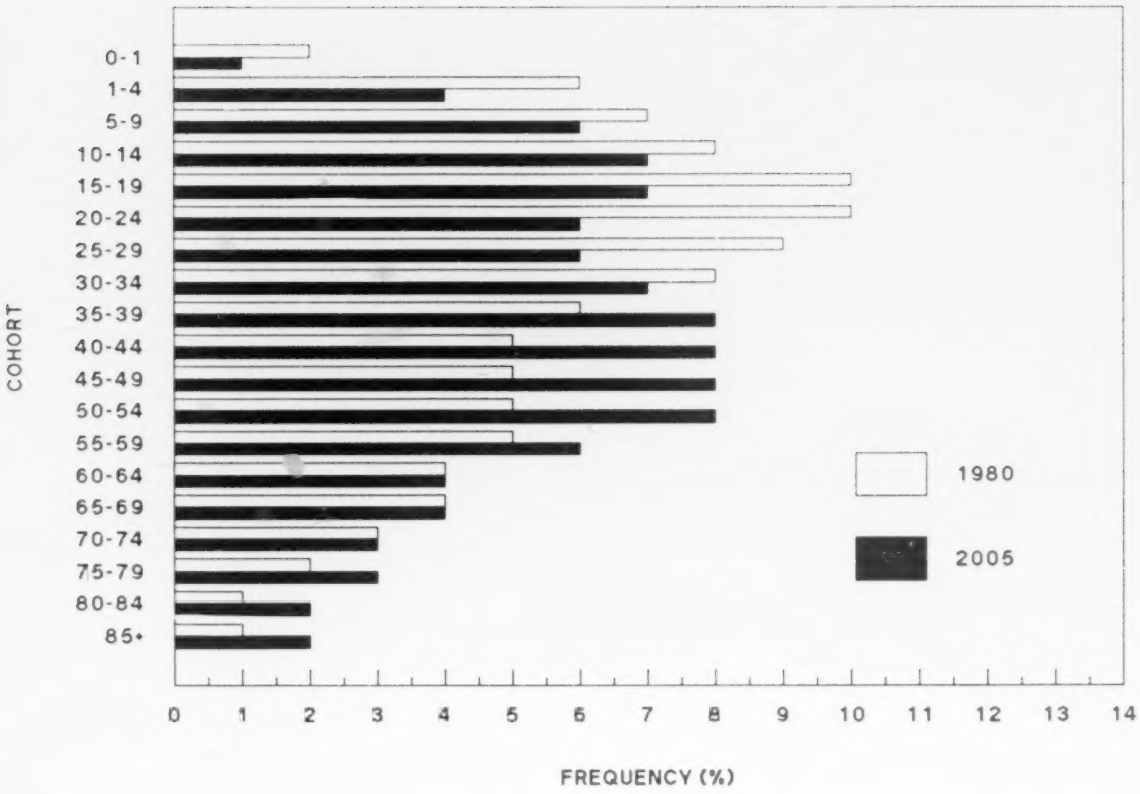

Figure 3. Age distribution of Vermont population, 1980 and 2005.

DETAILED TABLES

Projections of county populations by age cohort (Table 6) are based in large part on population estimates calculated since the 1980 US Census. Therefore, the level of certainty in these calculations is not large and planners should use these numbers as an indicator of broad trends only.

Population projections for each town to the year 2005 (Table 7) are based on the patterns of population growth between the years 1980 and 1987. These projections are useful to the extent that housing and employment patterns continue along the same trends as developed during the 1980's.

The sum of any given cohort across all counties in Table 6 was not controlled to the state total for the same cohort shown in Table 5. This may lead to discrepancies in the cohort totals between Tables 5 and 6. There may also be slight differences in the county totals between Tables 6 and 7 due to rounding errors.

METHODS

These population projections were developed using a three-step process.

The state population was predicted using an age/gender cohort model with fertility and survival rates projected from Vermont Department of Health estimates, and migration rates projected from US Bureau of the Census data and economic predictions.

The county population projections used a similar model but the projected cohort populations were controlled to the state totals.

The town population projections were based on the projected county population estimates and historical town population growth. There was no attempt to develop age cohort projections for individual towns because of small population totals.

State Projections

The state projections started with 1987 cohort data and generated annual projected age cohort populations through the year 2005. Population for each age group was estimated by determining the surviving, current-year population, subtracting the population which ages out of the cohort, adding the population which ages into the cohort, and adding the cohort's net migration (Appendix A). The process was repeated for projecting populations to the year 2005.

The number of newborns for each year was calculated as the sum of births from each female cohort. The number of male infants (ages 0-1) were calculated as 50.7% of the total births for each time period.

The survival rate for each gender/5-year age cohort was interpolated from the mean of the 1985 and 1986 Vermont Department of Health 10-year age cohort rates (Table 3). These figures have shown little variation in the last 8 years.

The fertility rates for the different age cohorts of women were taken as the average of Vermont Department of Health statistics for the years 1985-1987 (Table 2). An exception to this approach was used for the 15-19 year cohort, which was asssumed to decrease by 1% per year from the three year, 1985-1987 average.

Migration was first calculated as a statewide figure independent of age or gender. The US Bureau of the Census has yearly estimates of net migration for each state for the years 1975-1986. Migration was the factor which contributed the greatest variation to the population projections. Two different sets of assumptions were used to generate a range of expected future populations. The high growth scenario was based on the assumption that future economic growth will drive migration to Vermont. A time series regression of per capita income and net migration showed a positive correlation between income and migration for the years 1975 through 1986. Using the economic projections of the New England Economic Project for the years 1988-2000 and the regression equation, a figure for total net in-migration was determined for each year in the projections. Migration for the years 2001-2005 was assumed to remain constant at the same level as that for the year 2000. Although economic conditions are not the only factors contributing to migration, they were a useful proxy for calculating levels of in-migration. The low series projections assumed that net in-migration slows to the 1977-1987 10-year average. Table 4 shows the projected migration rates for each county.

The annual migration was distributed among age cohorts based on the proportion of the state population in each cohort. Past migration has not been evenly distributed among different cohorts. The last age-specific migration data cover the period 1970-1980, and the 1987 Vermont Department of Health estimates are based in part on these trends of the 1970's. A further reliance on the 1970's trends for future projections would lead to an unrealistic future distribution of population by age.

The absence of recent age cohort data for Vermont population estimates results in a low confidence in the projected cohort populations. The usefulness of these projections is limited to a description of the general trends caused by the aging of the post World War II Baby Boom.

County Projections

The county population projections used the same general approach as described for the state projections except for the fertility and migration rates.

Fertility

Fertility rates vary consistently among Vermont's counties. To account for this variability, the 1980-1987 eight-year average for each age cohort was compared with the state average over the same period. The difference between the state and county averages was applied to the state 1985-1987 three-year average to determine the county fertility rates for the years 1988 through 2005. Since 1985, Grand Isle statistics have been included with Franklin County and the Northeast Kingdom counties of Caledonia, Essex and Orleans were combined to produce a more stable and statistically significant sample size.

Migration

The Vermont Department of Health has calculated the net migration of population for each county. The different counties showed different rates of migration for the period 1980 to 1987, and these differences were assumed to continue into the future. The net migration for each county was determined by multiplying the projected migration for the state by the proportion of migration for each county (Appendix B).

The county population totals derived with the county-specific age/gender cohort model were controlled to the state total. The distribution of the adjusted county total to the different age cohorts was based on the 1980 county distribution and the projected changes in the state cohort (Appendix C). The confidence intervals for county cohort projections are larger than for state cohort projections.

Town Projections

The growth of individual towns is dependent on many factors that are not easily quantifiable with available data. In this set of projections, one of the factors used to determine future population was the slope of the regression of the population total for each town between 1980 through 1987. The other factors used included the total county growth as determined from the state and county projection models, and the 1987 estimate of each town's population (Appendix D). No age/gender cohort breakdown for towns was attempted because of small sample sizes.

Towns with decreasing populations showed unrealistic estimates in the high range series. To correct for these problems, the equation for high range estimates for five towns (Troy, Mt. Tabor, Proctor, Hancock and Plainfield) was modified (Appendix D). In the 4 counties affected by the change in method, the remaining towns required slight downward corrections to meet county totals.

APPENDICES

Appendix A

Age/Gender Cohort Model

$$N_c = N_s - N_o + N_i + M_c$$

With:

$$N_s = N_1 \cdot l_1$$

$$N_o = (N_1 + N_2)/(y_1 + y_2) \cdot (l_1 + l_2)/2$$

$$M_c = M \cdot N_1/N$$

Where:

l_1 = Survival rate of cohort

l_2 = Survival rate of succeeding cohort

M = Total net migration (all cohorts)

M_c = Net cohort migration

N = Total population

N_c = Projected cohort population

N_i = Population aging into cohort

N_o = Population aging out of cohort

N_s = Cohort population surviving at end of current year

N_1 = Cohort population

N_2 = Succeeding cohort population

y_1 = Number of years in cohort

y_2 = Number of years in succeeding cohort

The population aging into a cohort (N_i) is calculated in the same way as N_o, with N_2, y_2, and l_2 referring to the preceding, rather than succeeding, cohort.

Appendix B

Projected Migration Rates by County

Just as the cohort specific migration proportions cannot be assumed to continue at 1980 to 1987 levels, each county's proportion of state migration will change from current values.

The equation to assign the level of migration to each county is:

$$m = M \cdot (m' / M' + n_{87}/N_{87} \cdot (y - 1987))/(y - 1986)$$

Where:

- m = Projected county migration
- m' = County migration (1980-1987)
- M = Projected total net state migration
- M' = Total net state migration (1980-1987)
- n_{87} = County population (1987)
- N_{87} = Total state population (1987)
- y = Year of projection

Appendix C

County Age/Gender Cohort Projections

The projected population for each county is distributed to the age cohorts with the following equation:

$$n_c = n \cdot (N_c/N - N'_c/N' + n'_c/n')$$

Where:

- n = Projected county population total
- n' = 1980 county total population
- n_c = Projected cohort population
- n'_c = 1980 county cohort population
- N = Projected state population total
- N' = 1980 state total population
- N_c = Projected state population for cohort
- N'_c = 1980 state cohort population

Appendix D

Town Projections

The projected population for each town was determined with the following equation:

$$n = n_{87} + g \cdot (r/r + n_{87}/n_{87})/2$$

For towns with decreasing population (Hancock, Mt. Tabor, Plainfield, Proctor, Troy) the equation is:

$$n = n_{87} + g \cdot (r/r + (2 \cdot n_{87}/n_{87}))/3$$

Where: g = County growth (projected)

n = Projected town population

n_{87} = Estimated 1987 town population

n_{87} = Estimated 1987 county population

r = Town annual population change (from regression)

r = County annual population change (sum of r for county)
